Description

The highly integrated FSBH-series consists of an integrated current-mode Pulse Width Modulator (PWM) and an avalanche-rugged 700 V SenseFET. It is specifically designed for high-performance offline Switched-Mode Power Supplies (SMPS) with minimal external components.

The integrated PWM controller features include a proprietary green-mode function that provides off-time modulation to linearly decrease the switching frequency at light-load conditions to minimize standby power consumption. To avoid acoustic-noise problems, the minimum PWM frequency is set above 18 kHz. This green-mode function enables the power supply to 1/m[(p)-26(])27(ym[(.8(

Pin Definitions

Pin #	Name	Description
1	GND	**Ground**. SenseFET source terminal on primary side and internal controller ground.
2	VDD	**Power Supply**. The internal protection circuit disables PWM output as long as V_{DD} exceeds the OVP trigger point.

Absolute Maximum Ratings

Stresses exceeding the absolute maximum ratings may damage the device. The device may not function or be operable above the recommended operating conditions and stressing the parts to these levels is not recommended. In addition, extended exposure to stresses above the recommended operating conditions may affect device reliability. The absolute maximum ratings are stress ratings only.)

Green-Mode Operation

The FSBH-series uses feedback voltage (V_{FB}) as an indicator of the output load and modulates the PWM frequency, as shown in Figure 26, such that the switching frequency decreases as load decreases. In heavy-load conditions, the switching frequency is 100 kHz. Once V_{FB} decreases below V_{FB-N} (2.5 V), the PWM frequency starts to linearly decrease from 100 kHz to 18 kHz to reduce switching losses. As V_{FB} decreases below V_{FB-G} (2.0 V), the switching frequency is fixed at 18 kHz and the FSBH-series enters "deep" green mode to reduce the standby power consumption.

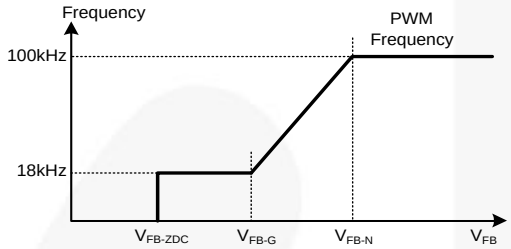

Figure 26. PWM Frequency

As V_{FB} decreases below V_{FB-ZDC} (1.6 V), the FSBH-series enters burst-mode operation. When V_{FB} drops below V_{FB-ZDC}, FSBH-series stops switching and the output voltage starts to drop, which causes the feedback voltage to rise. Once V_{FB} rises above V_{FB-ZDC}, switching resumes. Burst mode alternately enables and disables switching, thereby reducing switching loss to improve power saving, as shown in Figure 27.

H/L Line Over-Power Compensation

To limit the output power of the converter constantly, high/low line over-power compensation is included. Sensing the converter input voltage through the VIN pin, the high/low line compensation function generates a relative peak-current-limit threshold voltage for constant power control, as shown in Figure 28.
